

ABSTRACT

A resin-coated sheet (1) which comprises a fibrous sheet base (2) permeable to moisture and a resinous coating film (4) formed on at least one side of the base. The resinous coating film is one obtained by drying on the sheet base a coating film of an adhesive (4') comprising a vinyl acetate resin emulsion consisting mainly of the vinyl acetate resin and water. The resinous coating film has a smooth surface formed by covering the coating film of the adhesive with a moisture-impermeable release sheet (3) and peeling off the release sheet after the coating film has dried. When a moderate amount of water is given to the surface of this dried resinous coating film, the film recovers moderate tackiness and comes to have a tacky surface which makes the sheet easily and repeatedly strippable.
